Databases and the Doctrine ORM

4.2 version ▼

edit this page

Screencast

Do you prefer video tutorials? Check out the [Doctrine screencast series](#).

Symfony doesn't provide a component to work with the database, but it *does* provide tight integration with a third-party library called [Doctrine](#).

 **Note**

This article is all about using the Doctrine ORM. If you prefer to use raw database queries, see the "[How to Use Doctrine DBAL](#)" article instead.

You can also persist data to [MongoDB](#) using Doctrine ODM library. See the "[DoctrineMongoDBBundle](#)" documentation.

Installing Doctrine ¶

First, install Doctrine support via the ORM pack, as well as the MakerBundle, which will help generate some code:

```
$ composer require symfony/orm-pack
$ composer require symfony/maker-bundle --dev
```

Configuring the Database ¶

The database connection information is stored as an environment variable called `DATABASE_URL`. For development, you can find and customize this inside `.env`:

```
1 # .env (or override DATABASE_URL in .env.local to avoid committing your changes)
2
3 # customize this line!
4 DATABASE_URL="mysql://db_user:db_password@127.0.0.1:3306/db_name"
5
6 # to use sqlite:
7 # DATABASE_URL="sqlite:///kernel.project_dir%/var/app.db"
```

⚠ Caution

If the username, password, host or database name contain any character considered special in a URI (such as `!`, `@`, `$`, `#`, `/`), you must encode them. See [RFC 3986](#) for the full list of reserved characters or use the `urlencode` function to encode them. In this case you need to remove the `resolve:` prefix in `config/packages/doctrine.yaml` to avoid errors: `url: '%env(resolve:DATABASE_URL)%'`

Now that your connection parameters are setup, Doctrine can create the `db_name` database for you:

```
$ php bin/console doctrine:database:create
```

There are more options in `config/packages/doctrine.yaml` that you can configure, including your `server_version` (e.g. 5.7 if you're using MySQL 5.7), which may affect how Doctrine functions.

💡 Tip

There are many other Doctrine commands. Run `php bin/console list doctrine` to see a full list.

Creating an Entity Class ¶

Suppose you're building an application where products need to be displayed. Without even thinking about Doctrine or databases, you already know that you need a `Product` object to represent those products.

You can use the `make:entity` command to create this class and any fields you need. The command will ask you some questions - answer them like done below:

```
$ php bin/console make:entity

Class name of the entity to create or update:
> Product

New property name (press <return> to stop adding fields):
> name

Field type (enter ? to see all types) [string]:
> string

Field length [255]:
> 255

Can this field be null in the database (nullable) (yes/no) [no]:
> no

New property name (press <return> to stop adding fields):
> price

Field type (enter ? to see all types) [string]:
> integer

Can this field be null in the database (nullable) (yes/no) [no]:
> no

New property name (press <return> to stop adding fields):
>
(press enter again to finish)
```

New in version 1.3: The interactive behavior of the `make:entity` command was introduced in MakerBundle 1.3.

Woh! You now have a new `src/Entity/Product.php` file:

```
1  // src/Entity/Product.php
2  namespace App\Entity;
3
4  use Doctrine\ORM\Mapping as ORM;
5
6  /**
7   * @ORM\Entity(repositoryClass="App\Repository\ProductRepository")
8   */
9  class Product
10 {
11     /**
```

```

12     * @ORM\Id
13     * @ORM\GeneratedValue
14     * @ORM\Column(type="integer")
15     */
16     private $id;
17
18     /**
19     * @ORM\Column(type="string", length=255)
20     */
21     private $name;
22
23     /**
24     * @ORM\Column(type="integer")
25     */
26     private $price;
27
28     public function getId()
29     {
30         return $this->id;
31     }
32
33     // ... getter and setter methods
34 }

```

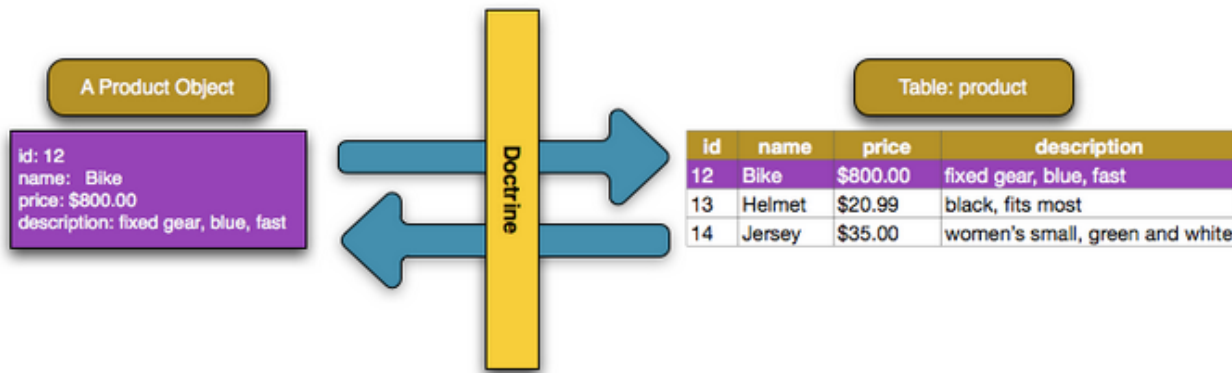

Note

Confused why the price is an integer? Don't worry: this is just an example. But, storing prices as integers (e.g. 100 = \$1 USD) can avoid rounding issues.

Caution

There is a [limit of 767 bytes for the index key prefix](#) when using InnoDB tables in MySQL 5.6 and earlier versions. String columns with 255 character length and utf8mb4 encoding surpass that limit. This means that any column of type string and unique=true must set its maximum length to 190. Otherwise, you'll see this error: "
[PDOException] SQLSTATE[42000]: Syntax error or access violation: 1071 Specified key was too long; max key length is 767 bytes".

This class is called an "entity". And soon, you'll be able to save and query Product objects to a `product` table in your database. Each property in the `Product` entity can be mapped to a column in that table. This is usually done with annotations: the `@ORM\...` comments that you see above each property:

The `make:entity` command is a tool to make life easier. But this is *your* code: add/remove fields, add/remove methods or update configuration.

Doctrine supports a wide variety of field types, each with their own options. To see a full list, check out [Doctrine's Mapping Types documentation](#). If you want to use XML instead of annotations, add `type: xml` and `dir:`

`'%kernel.project_dir%/config/doctrine'` to the entity mappings in your `config/packages/doctrine.yaml` file.

⚠ Caution

Be careful not to use reserved SQL keywords as your table or column names (e.g. `GROUP` or `USER`). See Doctrine's [Reserved SQL keywords documentation](#) for details on how to escape these. Or, change the table name with `@ORM\Table(name="groups")` above the class or configure the column name with the `name="group_name"` option.

Migrations: Creating the Database Tables/Schema ¶

The `Product` class is fully-configured and ready to save to a `product` table. If you just defined this class, your database doesn't actually have the `product` table yet. To add it, you can leverage the [DoctrineMigrationsBundle](#), which is already installed:

```
$ php bin/console make:migration
```

If everything worked, you should see something like this:

SUCCESS!

Next: Review the new migration "`src/Migrations/Version20180207231217.php`" Then: Run the migration with `php bin/console doctrine:migrations:migrate`

If you open this file, it contains the SQL needed to update your database! To run that SQL, execute your migrations:

```
$ php bin/console doctrine:migrations:migrate
```

This command executes all migration files that have not already been run against your database. You should run this command on production when you deploy to keep your production database up-to-date.

Migrations & Adding more Fields ¶

But what if you need to add a new field property to `Product`, like a `description`? You can edit the class to add the new property. But, you can also use `make:entity` again:

```
$ php bin/console make:entity

Class name of the entity to create or update
> Product

New property name (press <return> to stop adding fields):
> description

Field type (enter ? to see all types) [string]:
> text

Can this field be null in the database (nullable) (yes/no) [no]:
> no

New property name (press <return> to stop adding fields):
>
(push enter again to finish)
```

This adds the new `description` property and `getDescription()` and `setDescription()` methods:

```
1  // src/Entity/Product.php
2  // ...
3
4  class Product
5  {
6      // ...
7
8      /**
9       * @ORM\Column(type="text")
10      */
11     private $description;
12
13     // getDescription() & setDescription() were also added
14 }
```

The new property is mapped, but it doesn't exist yet in the `product` table. No problem! Generate a new migration:

```
$ php bin/console make:migration
```

This time, the SQL in the generated file will look like this:

```
1 ALTER TABLE product ADD description LONGTEXT NOT NULL
```

The migration system is *smart*. It compares all of your entities with the current state of the database and generates the SQL needed to synchronize them! Like before, execute your migrations:

```
$ php bin/console doctrine:migrations:migrate
```

This will only execute the *one* new migration file, because DoctrineMigrationsBundle knows that the first migration was already executed earlier. Behind the scenes, it manages a `migration_versions` table to track this.

Each time you make a change to your schema, run these two commands to generate the migration and then execute it. Be sure to commit the migration files and execute them when you deploy.

Tip

If you prefer to add new properties manually, the `make:entity` command can generate the getter & setter methods for you:

```
$ php bin/console make:entity --regenerate
```

If you make some changes and want to regenerate *all* getter/setter methods, also pass `--overwrite`.

Persisting Objects to the Database ¶

It's time to save a `Product` object to the database! Let's create a new controller to experiment:

```
$ php bin/console make:controller ProductController
```

Inside the controller, you can create a new `Product` object, set data on it, and save it!

```
1 // src/Controller/ProductController.php
2 namespace App\Controller;
3
4 // ...
5 use Symfony\Component\HttpFoundation\Response;
6
7 use App\Entity\Product;
8
9 class ProductController extends AbstractController
10 {
11     /**
12      * @Route("/product", name="product")
```

```

13      */
14      public function index()
15      {
16          // you can fetch the EntityManager via $this->getDoctrine()
17          // or you can add an argument to your action: index(EntityManagerInterface $entityManager)
18          $entityManager = $this->getDoctrine()->getManager();
19
20          $product = new Product();
21          $product->setName('Keyboard');
22          $product->setPrice(1999);
23          $product->setDescription('Ergonomic and stylish!');
24
25          // tell Doctrine you want to (eventually) save the Product (no queries yet)
26          $entityManager->persist($product);
27
28          // actually executes the queries (i.e. the INSERT query)
29          $entityManager->flush();
30
31          return new Response('Saved new product with id '.$product->getId());
32      }
33  }

```

Try it out!

<http://localhost:8000/product>

Congratulations! You just created your first row in the `product` table. To prove it, you can query the database directly:

```

$ php bin/console doctrine:query:sql 'SELECT * FROM product'

# on Windows systems not using Powershell, run this command instead:
# php bin/console doctrine:query:sql "SELECT * FROM product"

```

Take a look at the previous example in more detail:

- **line 18** The `$this->getDoctrine()->getManager()` method gets Doctrine's *entity manager* object, which is the most important object in Doctrine. It's responsible for saving objects to, and fetching objects from, the database.
- **lines 20-23** In this section, you instantiate and work with the `$product` object like any other normal PHP object.
- **line 26** The `persist($product)` call tells Doctrine to "manage" the `$product` object. This does **not** cause a query to be made to the database.
- **line 29** When the `flush()` method is called, Doctrine looks through all of the objects that it's managing to see if they need to be persisted to the database. In this example, the `$product` object's data doesn't exist in the database, so the entity manager executes an `INSERT` query, creating a new row in the `product` table.

Note

If the `flush()` call fails, a `Doctrine\ORM\ORMException` exception is thrown. See [Transactions and Concurrency](#).

Whether you're creating or updating objects, the workflow is always the same: Doctrine is smart enough to know if it should INSERT or UPDATE your entity.

Fetching Objects from the Database ¶

Fetching an object back out of the database is even easier. Suppose you want to be able to go to `/product/1` to see your new product:

```
1  // src/Controller/ProductController.php
2  // ...
3
4  /**
5   * @Route("/product/{id}", name="product_show")
6   */
7  public function show($id)
8  {
9      $product = $this->getDoctrine()
10         ->getRepository(Product::class)
11         ->find($id);
12
13      if (!$product) {
14          throw $this->createNotFoundException(
15              'No product found for id '.$id
16          );
17      }
18
19      return new Response('Check out this great product: '.$product->getName());
20
21      // or render a template
22      // in the template, print things with {{ product.name }}
23      // return $this->render('product/show.html.twig', ['product' => $product]);
24  }
```

Try it out!

<http://localhost:8000/product/1>

When you query for a particular type of object, you always use what's known as its "repository". You can think of a repository as a PHP class whose only job is to help you fetch entities of a certain class.

Once you have a repository object, you have many helper methods:

```
1  $repository = $this->getDoctrine()->getRepository(Product::class);
2
3  // look for a single Product by its primary key (usually "id")
4  $product = $repository->find($id);
5
6  // look for a single Product by name
7  $product = $repository->findOneBy(['name' => 'Keyboard']);
8  // or find by name and price
9  $product = $repository->findOneBy([
```

```

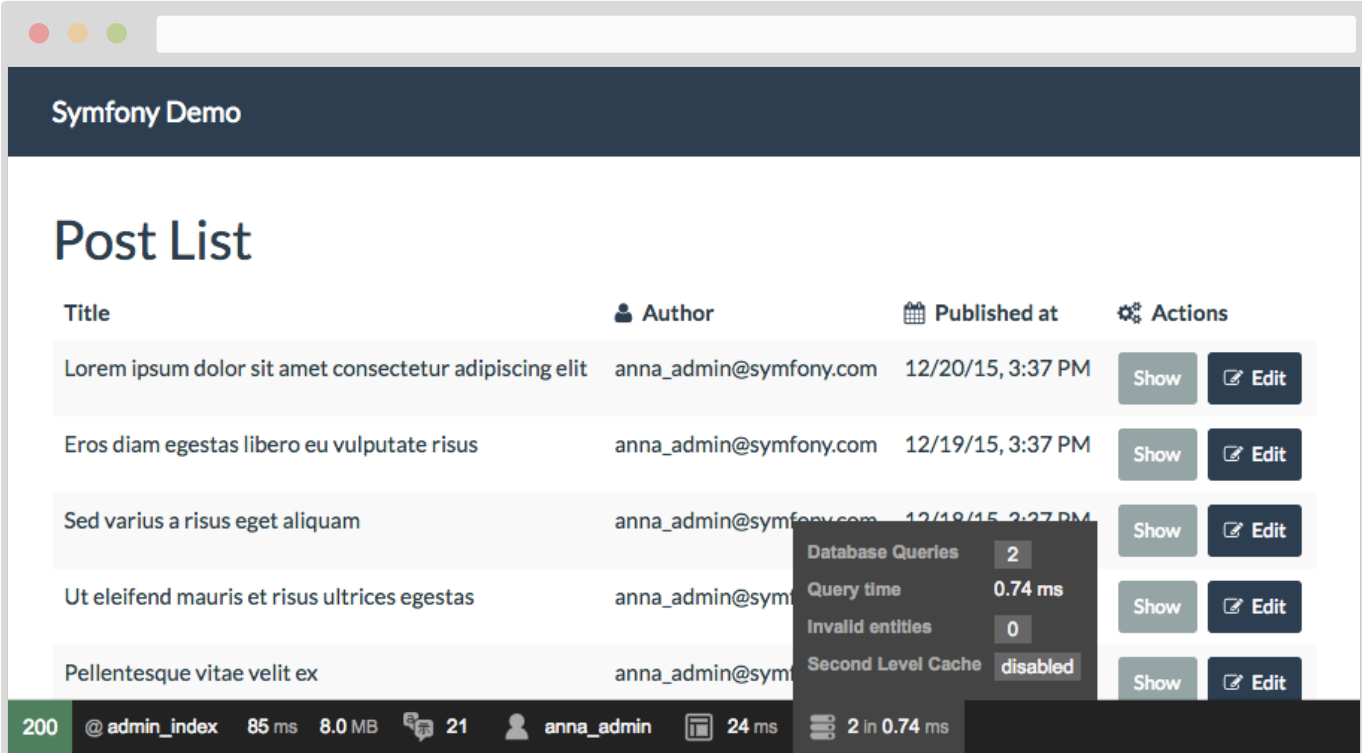

10     'name' => 'Keyboard',
11     'price' => 1999,
12 ];
13
14 // look for multiple Product objects matching the name, ordered by price
15 $products = $repository->findBy(
16     ['name' => 'Keyboard'],
17     ['price' => 'ASC']
18 );
19
20 // look for *all* Product objects
21 $products = $repository->findAll();

```

You can also add *custom* methods for more complex queries! More on that later in the [Querying for Objects: The Repository](#) section.

Tip

When rendering an HTML page, the web debug toolbar at the bottom of the page will display the number of queries and the time it took to execute them:

The screenshot shows a web application titled "Symfony Demo" with a "Post List" section. The list contains five posts, each with a title, author (anna_admin@symfony.com), and published date. Each post has "Show" and "Edit" buttons. At the bottom, the Symfony Profiler web debug toolbar is visible, showing 200 requests, 85 ms execution time, 8.0 MB memory usage, 21 messages, and 2 database queries in 0.74 ms. A tooltip for the database queries is also shown, indicating 2 queries, 0.74 ms query time, 0 invalid entities, and a disabled second level cache.

Title	Author	Published at	Actions
Lorem ipsum dolor sit amet consectetur adipiscing elit	anna_admin@symfony.com	12/20/15, 3:37 PM	Show Edit
Eros diam egestas libero eu vulputate risus	anna_admin@symfony.com	12/19/15, 3:37 PM	Show Edit
Sed varius a risus eget aliquam	anna_admin@symfony.com	12/18/15, 3:37 PM	Show Edit
Ut eleifend mauris et risus ultrices egestas	anna_admin@symfony.com	12/17/15, 3:37 PM	Show Edit
Pellentesque vitae velit ex	anna_admin@symfony.com	12/16/15, 3:37 PM	Show Edit

Database Queries 2
Query time 0.74 ms
Invalid entities 0
Second Level Cache disabled

200 @ admin_index 85 ms 8.0 MB 21 anna_admin 24 ms 2 in 0.74 ms

If the number of database queries is too high, the icon will turn yellow to indicate that something may not be correct. Click on the icon to open the Symfony Profiler and see the exact queries that were executed. If you don't see the web debug toolbar, try running `composer require --dev symfony/profiler-pack` to install it.

Automatically Fetching Objects (ParamConverter) ¶

In many cases, you can use the [SensioFrameworkExtraBundle](#) to do the query for you automatically! First, install the bundle in case you don't have it:

```
$ composer require sensio/framework-extra-bundle
```

Now, simplify your controller:

```
1  // src/Controller/ProductController.php
2
3  use App\Entity\Product;
4  // ...
5
6  /**
7   * @Route("/product/{id}", name="product_show")
8   */
9  public function show(Product $product)
10 {
11     // use the Product!
12     // ...
13 }
```

That's it! The bundle uses the `{id}` from the route to query for the `Product` by the `id` column. If it's not found, a 404 page is generated.

There are many more options you can use. Read more about the [ParamConverter](#).

Updating an Object ¶

Once you've fetched an object from Doctrine, you interact with it the same as with any PHP model:

```
1  /**
2   * @Route("/product/edit/{id}")
3   */
4  public function update($id)
5  {
6      $entityManager = $this->getDoctrine()->getManager();
7      $product = $entityManager->getRepository(Product::class)->find($id);
8
9      if (!$product) {
10         throw $this->createNotFoundException(
11             'No product found for id '.$id
12         );
13     }
14
15     $product->setName('New product name!');
16     $entityManager->flush();
17
18     return $this->redirectToRoute('product_show', [
19         'id' => $product->getId()
20     ]);
21 }
```

Using Doctrine to edit an existing product consists of three steps:

1. fetching the object from Doctrine;
2. modifying the object;
3. calling `flush()` on the entity manager.

You can call `$entityManager->persist($product)`, but it isn't necessary: Doctrine is already "watching" your object for changes.

Deleting an Object ¶

Deleting an object is very similar, but requires a call to the `remove()` method of the entity manager:

```
$entityManager->remove($product);  
$entityManager->flush();
```

As you might expect, the `remove()` method notifies Doctrine that you'd like to remove the given object from the database. The `DELETE` query isn't actually executed until the `flush()` method is called.

Querying for Objects: The Repository ¶

You've already seen how the repository object allows you to run basic queries without any work:

```
// from inside a controller  
$repository = $this->getDoctrine()->getRepository(Product::class);  
  
$product = $repository->find($id);
```

But what if you need a more complex query? When you generated your entity with `make:entity`, the command also generated a `ProductRepository` class:

```
1  // src/Repository/ProductRepository.php  
2  namespace App\Repository;  
3  
4  use App\Entity\Product;  
5  use Doctrine\Bundle\DoctrineBundle\Repository\ServiceEntityRepository;  
6  use Symfony\Bridge\Doctrine\RegistryInterface;  
7  
8  class ProductRepository extends ServiceEntityRepository  
9  {  
10     public function __construct(RegistryInterface $registry)  
11     {  
12         parent::__construct($registry, Product::class);  
13     }  
14 }
```

When you fetch your repository (i.e. `->getRepository(Product::class)`), it is *actually* an instance of *this* object! This is because of the `repositoryClass` config that was generated at the top of your `Product` entity class.

Suppose you want to query for all Product objects greater than a certain price. Add a new method for this to your repository:

```
1  // src/Repository/ProductRepository.php
2
3  // ...
4  class ProductRepository extends ServiceEntityRepository
5  {
6      public function __construct(RegistryInterface $registry)
7      {
8          parent::__construct($registry, Product::class);
9      }
10
11     /**
12      * @param $price
13      * @return Product[]
14      */
15     public function findAllGreaterThanPrice($price): array
16     {
17         // automatically knows to select Products
18         // the "p" is an alias you'll use in the rest of the query
19         $qb = $this->createQueryBuilder('p')
20             ->andWhere('p.price > :price')
21             ->setParameter('price', $price)
22             ->orderBy('p.price', 'ASC')
23             ->getQuery();
24
25         return $qb->execute();
26
27         // to get just one result:
28         // $product = $qb->setMaxResults(1)->getOneOrNullResult();
29     }
30 }
```

This uses Doctrine's [Query Builder](#): a very powerful and user-friendly way to write custom queries. Now, you can call this method on the repository:

```
1  // from inside a controller
2  $minPrice = 1000;
3
4  $products = $this->getDoctrine()
5      ->getRepository(Product::class)
6      ->findAllGreaterThanPrice($minPrice);
7
8  // ...
```

If you're in a [Injecting Services/Config into a Service](#), you can type-hint the `ProductRepository` class and inject it like normal.

For more details, see the [Query Builder](#) Documentation from Doctrine.

Querying with DQL or SQL ¶

In addition to the query builder, you can also query with [Doctrine Query Language](#):

```
1  // src/Repository/ProductRepository.php
2  // ...
3
4  public function findAllGreaterThanPrice($price): array
5  {
6      $entityManager = $this->getEntityManager();
7
8      $query = $entityManager->createQuery(
9          'SELECT p
10         FROM App\Entity\Product p
11         WHERE p.price > :price
12         ORDER BY p.price ASC'
13      )->setParameter('price', $price);
14
15      // returns an array of Product objects
16      return $query->execute();
17  }
```

Or directly with SQL if you need to:

```
1  // src/Repository/ProductRepository.php
2  // ...
3
4  public function findAllGreaterThanPrice($price): array
5  {
6      $conn = $this->getEntityManager()->getConnection();
7
8      $sql = '
9          SELECT * FROM product p
10         WHERE p.price > :price
11         ORDER BY p.price ASC
12         ';
13      $stmt = $conn->prepare($sql);
14      $stmt->execute(['price' => $price]);
15
16      // returns an array of arrays (i.e. a raw data set)
17      return $stmt->fetchAll();
18  }
```

With SQL, you will get back raw data, not objects (unless you use the [NativeQuery](#) functionality).

Configuration ¶

See the [Doctrine config reference](#).

Relationships and Associations ¶

Doctrine provides all the functionality you need to manage database relationships (also known as associations), including `ManyToOne`, `OneToMany`, `OneToOne` and `ManyToMany` relationships.

For info, see [How to Work with Doctrine Associations / Relations](#).

Dummy Data Fixtures ¶

Doctrine provides a library that allows you to programmatically load testing data into your project (i.e. "fixture data"). Install it with:

```
$ composer require doctrine/doctrine-fixtures-bundle --dev
```

Then, use the `make:fixtures` command to generate an empty fixture class:

```
$ php bin/console make:fixtures

The class name of the fixtures to create (e.g. AppFixtures):
> ProductFixture
```

Customize the new class to load `Product` objects into Doctrine:

```
1  // src/DataFixtures/ProductFixture.php
2  namespace App\DataFixtures;
3
4  use Doctrine\Bundle\FixturesBundle\Fixture;
5  use Doctrine\Common\Persistence\ObjectManager;
6
7  class ProductFixture extends Fixture
8  {
9      public function load(ObjectManager $manager)
10     {
11         $product = new Product();
12         $product->setName('Priceless widget!');
13         $product->setPrice(14.50);
14         $product->setDescription('Ok, I guess it *does* have a price');
15         $manager->persist($product);
16
17         // add more products
18
19         $manager->flush();
20     }
21 }
```

Empty the database and reload *all* the fixture classes with:

```
$ php bin/console doctrine:fixtures:load
```

For information, see the "[DoctrineFixturesBundle](#)" documentation.
